The mathematics behind a perfect match

It's a problem that has had many names — the secretary problem, the Balducci-Lidov problem and the optimal stopping problem, but it's obvious that you need to decide when to stop dating and settle down. “Settle down early and you might forego the chance of a more perfect match later on. Wait too long to commit, and all the great ones might be gone. You don't want to marry the first person you meet, but you also don't want to wait too long,” writes Alan Swanson, as she describes the mathematics behind finding the best spouse.

The spouse problem is an old one, and has a solution — a simple mathematical rule. “In the scenario, you're choosing from a set number of options. For example, let's say there is a total of 10 potential mates who you could seriously date and settle down with in your lifetime. If you could only see them all together at the same time, you'd have no problem picking out the best. But this isn't how a lifetime of dating works, obviously,” writes Swanson.

The problem, of course, is that mates don't appear together but at random. And of course, once you've rejected someone, it can be embarrassing — if not impossible, to go back.

The answer lies in probability — and its mathematics. To find the perfect partner, you have to date and reject the first 37% of the group, your total lifetime mates. Then find the next person who is better than anyone you've ever dated before. Naturally, for this to work in real life, you need to know how many mates you will have, but you can't make a guess.

There are risks, of course. “There's the risk, for example, that the first person you date isn't in your perfect percent. If you follow the rule, you'll reject that person anyway. And as you continue to date other people, no one will ever measure up to your first love, and you'll end up rejecting everyone, and end up alone with your cats. Of course, some people may find cats preferable to boyfriends or girlfriends anyway,” writes Swanson.

Result: 144—competitive/optimal and truthful [V, Coupechoux]

when is a reverse auction truthful ?

R. Myerson

Monotonicity - if an agent is selected with bid b , then he is always selected if he bids below b

Critical Price - there exists a threshold price such that if an agent bids above it he is never selected

I don't always fail

But when I do, I make sure that you're in the middle of something important.

Secretary Problem

1. Why arbit doesn't work
2. Randomized Model
3. Simple Algo 1/2

Sec. Prob as Matching with only one left vertex

Bipartite matching problem

Greedy 1/2 algo

Philosophy from Sec problem Hide the first half Set the price and select above the threshold

Wireless Problem -BS assoc

Equal weight case- Offline is to keep one per good BS

Use the same philosophy show that OFF < Max Weight

Designate one BS as garbage and do Online Matching on the rest Guarantee $(M-1)/8M$
